### 1 Pointer Analysis

The states of the concrete semantics used in this section are functions  $S = \text{Loc} \to \text{Loc} \cup Z$ . The abstract domain in this section is  $A = 2^{\text{Var}^* \times \text{Var}^*}$  and the abstraction function  $(\alpha)$  is defined by means of an extraction function  $(\beta)$ , where  $\beta(s) = \{(x,y) \mid s(loc(x)) = loc(y)\}$ . The function  $loc: \text{Var}^* \to \text{Loc}$  returns the "address" of each variable.

Recall that as usual in cases in which the Galois connection induced by an extraction function,  $\alpha(S) = \bigcup \{\beta(s) \mid s \in S\}$ , and  $\gamma(a) = \{s \in 2^{\operatorname{Var}^* \times \operatorname{Var}^*} \mid \beta(s) \subseteq a\}$ .

#### 1.1 Question 1

The concrete semantics of the statement x = y is

$$\llbracket x = y \rrbracket(s) = s[loc(x) \mapsto s(loc(y))]$$

. The abstract transformer associated with this statement is

$$[x = y]^{\sharp}(a) = a \setminus \{(x, z) \mid z \in \text{Var}^*\} \cup \{(x, w) \mid (y, w) \in a\}$$

. Show that the abstract transformer is the best, e.g.

$$[x = y]^{\sharp}(a) = \alpha(\{[x = y]](s) \mid s \in \gamma(a)\})$$

for any  $a \in A$ .

*Proof.* We'll show equality by means of bi-directional set inclusion.

**Direction 1**  $[\![x = y]\!]^{\sharp}(a) \subseteq \alpha(\{[\![x = y]\!](s) \mid s \in \gamma(a)\})$ 

Let  $\Delta \in \llbracket x = y \rrbracket^{\sharp}(a) = a \setminus \{(x, z) \mid z \in \operatorname{Var}^*\} \cup \{(x, w) \mid (y, w) \in a\}$ , we'll treat 2 cases:

•  $\Delta = (x, w)$  then from abstract transformer definition exists (y, w) in a. Let us construct a concrete state s in the following form: s(loc(y)) = loc(w) and undefined for all other symbols. It holds that  $\beta(s) = \{(y, w)\} \subseteq a$  and therefore  $s \in \gamma(a)$ .

We now use the transformer on s and get  $s' = s[loc(x) \mapsto s(loc(y))] = s[loc(x) \mapsto loc(w)]$ . We got  $s' \in \{[x = y](s) \mid s \in \gamma(a)\}$  and also s'(loc(x)) = loc(w).

Finally, it holds that

$$\Delta = (x, w) \in \beta(s') = \alpha(\lbrace \llbracket x = y \rrbracket(s) \mid s \in \gamma(a) \rbrace)$$

•  $\Delta = (z, w)$  where  $z \neq x$  then from abstract transformer definition  $(z, y) \in a$ .

From that we will construct a concrete state s. It will be defined as s(loc(z)) = loc(w) and undefined for all other symbols, it holds that  $\beta(s) = \{(z, w)\} \subseteq a$  thus  $s \in \gamma(a)$ .

If we transform s with [x = y] we'll get  $s' = s[loc(x) \mapsto s(loc(y))]$ .

It is true that  $s' \in \{ [x = y](s) \mid s \in \gamma(a) \}$ , and s'(loc(w)) = loc(z) therefore:

$$\Delta = (w, z) \in \beta(s') = \alpha(\lbrace s' \rbrace) \subseteq \alpha(\lbrace \llbracket x = y \rrbracket(s) \mid s \in \gamma(a) \rbrace)$$

Dmitry Kuznetsov 322081183

**Direction 2**  $[x = y]^{\sharp}(a) \supseteq \alpha(\{[x = y]](s) \mid s \in \gamma(a)\})$ 

Let  $\Delta \in \alpha(\{[x = y]](s) \mid s \in \gamma(a)\})$  then exists  $s' \in \{[x = y]](s) \mid s \in \gamma(a)\}$  s.t.  $\Delta \in \beta(s') = \{(a,b) \mid s'(loc(a)) = loc(b)\}$ . From the original equation we also know that exists  $s \in \gamma(a)$  s.t.  $s' = s[loc(x) \mapsto s(loc(y))]$ . Similarly, we'll treat 2 cases here:

•  $\Delta = (x,z)$  then s'(loc(x)) = loc(z). It then must hold that s(loc(y)) = loc(z)(as  $s' = s[loc(x) \mapsto s(loc(y))]$ ).

Therefore,  $(y, z) \in \beta(s) \subseteq a$ . Knowing that  $(y, z) \in a$  we can deduce that

$$(x, z) \in \{(x, w) \mid (y, w) \in a\} \subseteq [[x = y]]^{\sharp}(a)$$

•  $\Delta = (w, z)$  for any  $w \neq z$  then s'(loc(w)) = loc(z) and from s''s relation with s also s(loc(w)) = loc(z).

Therefore  $(w, z) \in \beta(s) \subseteq a$ . Knowing that  $(w, z) \in a$  we can deduce that  $\Delta \notin \{(x, z) \mid z \in \text{Var}^*\}$ therefore  $\Delta \in [x = y]^{\sharp}(a)$ .

#### 1.2 Question 2

The abstract transformer of simple assignment

$$[x = y]^{\sharp}(a) = a \setminus \{(x, z) \mid z \in Var^*\} \cup \{(x, w) \mid (y, w) \in a\}$$

is distributive, i.e.,

$$\forall a_1, a_2 \in A : [\![x = y]\!]^{\sharp}(a_1) \sqcup [\![x = y]\!]^{\sharp}(a_2) = [\![x = y]\!]^{\sharp}(a_1 \sqcup a_2)$$

Proof.

$$c[[x = y]]^{\sharp}(a_{1}) \sqcup [[x = y]]^{\sharp}(a_{2}) =$$

$$= (a_{1} \setminus \{(x, z) \mid z \in \operatorname{Var}^{*}\} \cup \{(x, w) \mid (y, w) \in a_{1}\}) \cup (a_{2} \setminus \{(x, z) \mid z \in \operatorname{Var}^{*}\} \cup \{(x, w) \mid (y, w) \in a_{2}\})$$

$$= ((a_{1} \cup a_{2}) \setminus \{(x, z) \mid z \in \operatorname{Var}^{*}\}) \cup \{(x, w) \mid (y, w) \in (a_{1} \cup a_{2})\}$$

$$= ((a_{1} \sqcup a_{2}) \setminus \{(x, z) \mid z \in \operatorname{Var}^{*}\}) \cup \{(x, w) \mid (y, w) \in (a_{1} \sqcup a_{2})\}$$

$$= [[x = y]]^{\sharp}(a_{1} \sqcup a_{2})$$

#### 1.3 Question 3

The abstract transformer of the statement

$$[\![*x=y]\!]^\sharp(a)=a\cup\{(t,z)\mid (x,t)\in a, (y,z)\in a\}$$

is not distributive, i.e. exists  $a_1, a_2 \in A$  s.t.

$$[\![*x = y]\!]^{\sharp}(a_1) \sqcup [\![*x = y]\!]^{\sharp}(a_2) \neq [\![*x = y]\!]^{\sharp}(a_1 \sqcup a_2)$$

## Problem Set 2

*Proof.* We'll show the sets are not equal by showing elements present in  $[\![*x = y]\!]^{\sharp}(a_1 \sqcup a_2)$  but not in  $[\![*x = y]\!]^{\sharp}(a_1) \sqcup [\![*x = y]\!]^{\sharp}(a_2)$ . Let  $a_1$  s.t.

- $(x, t_1), (y, w_1) \in a_1$
- $(x, t_2), (y, w_2) \notin a_1$

additionally, let  $a_2$  s.t.

- $(x, t_1), (y, w_1) \notin a_2$
- $(x, t_2), (y, w_2) \in a_2$

then, it holds that:

- $(t_1, w_1) \in [x = y]^{\sharp}(a_1)$
- $(t_2, w_2) \in [\![ *x = y ]\!]^{\sharp} (a_2)$
- $(t_2, w_2) \notin [[*x = y]]^{\sharp}(a_1)$
- $(t_1, w_1) \notin [[*x = y]]^{\sharp}(a_2)$

therefore also  $(t_2, w_2), (t_1, w_1) \notin [\![*x = y]\!]^{\sharp}(a_1) \sqcup [\![*x = y]\!]^{\sharp}(a_2).$ Conversely,  $(t_2, w_2), (t_1, w_1) \in [\![*x = y]\!]^{\sharp}(a_1 \sqcup a_2).$ 

## 2 Shape Analysis

In the 3-valued logic framework for shape analysis, the user needs to provide the update formulae which describe the effect of every program statement on the core and instrumentation predicates. In the class, we defined at the update formulae for the core predicates for list-manipulating programs. Define the update formulae for the instrumentation predicates capturing the properties: reach-ability from variable x, heap-sharing (is-shared), and cyclicity for list manipulating programs. Assume that the pointer variables of the program are x, y and z.

- $r_x(v)$  is the predicate that means that node v is reachable from variable x. First, let us define the update formulae for statements that do not change next predicate:
  - $-\mathbf{x} = \text{NULL}$ :  $r'_{x}(v) = 0$

x is null, therefore no node is reachable.

- x = malloc():

$$r'_x(v) = x(v) = isNew(v)$$

**x** is a newly allocated variable, therefore only its node is reachable.

- x = y:

$$r_x'(v) = r_y(v)$$

A node v is reachable from x if and only if it is reachable from y.

- x = y - > next:

$$r'_x(v) = (\neg y(v) \land r_y(v)) \lor (y(v) \land c(v))$$

A node v is reachable from x if it is reachable from y and is not y's node, unless y's node is on a cycle and hence also reachable from y-> next.

Now, consider the case x->next=y. Apart from  $r_x$  being updated, for every other variable z we need to update  $r_z$ . We break it into two statements x->next=NULL; x->next=y. The update formula for the second statement assumes that x->next is null.

- x- > next = NULL:

$$* r'_r(v) = x(v)$$

Only x's node is now reachable from x.

$$* r'_z(v) = \begin{cases} \exists v'.x(v') \land n^*(v',v), & \text{if } (\exists v'.x(v') \land r_z(v')) \land r_x(v) \land c(v) \\ 0, & \text{if } (\exists v'.x(v') \land r_z(v')) \land r_x(v) \land \neg c(v) \\ r_z(v), & \text{if } \neg (\exists v'.x(v') \land r_z(v')) \lor \neg r_x(v) \end{cases}$$

If  $\mathbf{x}$ 's node is reachable from  $\mathbf{z}$  (denoted by  $\exists v'.x(v') \land r_z(v')$ ), and v was reachable from  $\mathbf{x}$ , and v was part of a cycle, we must compute  $r'_z(v)$  anew, because it might be the case that v is reachable from  $\mathbf{z}$  after  $\mathbf{x}$ , so it won't be reachable any longer, or before  $\mathbf{x}$ , and it will still be reachable.

If  $\mathbf{x}$ 's node is reachable from  $\mathbf{z}$ , and v was reachable from  $\mathbf{x}$ , and v was not part of a cycle, it won't be reachable any longer.

Otherwise, x's node is not reachable from z, or v was not reachable from x, so executing the statement won't change  $r_z(v)$ .

-x->next=y:

$$* r'_x(v) = x(v) \lor r_y(v)$$

x's node is reachable along with nodes that are reachable from y.

$$* r'_z(v) = (\exists v'. x(v') \land r_z(v')) \land r_y(v)$$

A node v is reachable if x is reachable from z and v is reachable from y

• c(v) is the predicate that means that node v is part of a cycle. Note that statements that do not change next predicate do not affect c(v). So we consider only x - > next = y. Again we break it into two statements

$$x- > next = NULL; x- > next = y.$$

$$\begin{aligned} & - \mathbf{x} - > \mathbf{next} = \mathbf{NULL:} \\ & c'(v) = \begin{cases} 0, & \text{if } \exists v'. x(v') \land r_x(v) \land c(v') \\ c(v), & \text{otherwise} \end{aligned}$$

If v was reachable from x's node and x's node was on a cycle, it means that v was on that cycle as well and now the cycle is cut. Otherwise the value is unchanged

$$- x -> \text{next} = y:$$

$$c'(v) = \begin{cases} 1, & \text{if } \exists v'. x(v') \land r_y(v') \land r_y(v) \\ c(v), & \text{otherwise} \end{cases}$$

If v is reachable from y's node and also x's node is reachable from y's node, it means that a new cycle is created with v on it. Otherwise the value is unchanged

• is(v) is the predicate that means that at least two different nodes point with next predicate to v (v is heap-shared). Note that statements that do not change next do not affect is(v). So we consider only x->next=y. Again we break it into two statements

$$x- > next = NULL; x- > next = y.$$

$$\begin{aligned} & - \mathbf{x} - > \mathbf{next} = \mathbf{NULL:} \\ & is'(v) = \begin{cases} \exists v_1, v_2. n(v_1, v) \land n(v_2, v) \land v_1 \neq v_2, & \text{if } (\exists v'. x(v') \land n(v', v)) \land is(v) \\ is(v), & \text{otherwise} \end{aligned}$$

If x's node pointed directly to v and is(v) = 1, we have to recompute is(v) since now it might be pointed by less than two nodes. Otherwise the value is unchanged.

$$- \mathbf{x} - > \mathbf{next} = \mathbf{y}:$$
 
$$is'(v) = \begin{cases} \exists v_1, v_2. n(v_1, v) \land n(v_2, v) \land v_1 \neq v_2, & \text{if } y(v) \land \neg is(v) \\ is(v), & \text{otherwise} \end{cases}$$

If we happen to update y's node and also is(v) = 0, we have to recompute is(v) since now it might be pointed by two different nodes. Otherwise the value is unchanged.

### 3 Owiki Gries Logic

Give a (non-trivial) specification for the following program and prove it using Owicki-Griel logic

$${X = A \land Y = B}x := X; Y := 1 | y := Y; X := x \dots$$

*Proof.* We will prove the following specification for the program:

$$\{ X = A \land Y = B \} x := X; Y := 1 | |y := Y; X := x \{ x = A \lor y = B \}$$

First, add two auxiliary variables  $done_0$  and  $done_1$  that record the state of execution of first and second statements accordingly. Now, rewrite the program as:

$$done_0 = 0; done_1 = 0; (x := X; (Y, done_0) := (1, 1)||y := Y; (X, done_1) := (x, 1)|$$

and let

$$S_{0} = x := X; (Y, done_{0}) := (1, 1)$$

$$S_{1} = y := Y; (X, done_{1}) := (x, 1)$$

$$S_{00} = x := X$$

$$S_{01} = (Y, done_{0}) := (1, 1)$$

$$S_{10} = y := Y$$

$$S_{11} = (X, done_{1}) := (x, 1)$$

Now we can define the pre conditions of each sub statement:

$$P_{00} = (done_0 = 0 \land (done_1 = 0 \to X = A) \land (done_1 = 1 \to (x = A \lor y = B)))$$

$$P_{01} = (done_0 = 0 \land (done_1 = 0 \to x = A) \land (done_1 = 1 \to (x = A \lor y = B)))$$

$$P_{10} = (done_1 = 0 \land (done_0 = 0 \to Y = B) \land (done_0 = 1 \to (x = A \lor y = B)))$$

$$P_{11} = (done_1 = 0 \land (done_0 = 0 \to y = B) \land (done_0 = 1 \to (x = A \lor y = B)))$$

Also, define the post conditions:

$$Q_0 = (done_0 = 1 \land (done_1 = 0 \to x = A) \land (done_1 = 1 \to (x = A \lor y = B)))$$
  
 $Q_1 = (done_1 = 1 \land (done_0 = 0 \to y = B) \land (done_0 = 1 \to (x = A \lor y = B)))$ 

 $P_{00}$  and  $P_{10}$  describe the state of events before the assignment to x or y took place, and  $P_{10}$  and  $P_{11}$  after, accordingly. After the counterpart statement is done, we can have both x and y updated, or only one of them.

Now we wish to show that  $S_0$  and  $S_1$  are interference free. To do this we need to prove the following to show that  $S_0$  is interference free:

$$\{P_{00} \wedge Q_1\} S_0 \{Q_1\}$$
 (1)

$$\{P_{00} \wedge P_{10}\} S_0 \{P_{10}\}\$$
 (2)

$$\{P_{00} \wedge P_{11}\} S_0 \{P_{11}\}\$$
 (3)

Theorem (1) is the post condition test and theorems (2) and (3) are the pre-condition tests that check each "sub" pre-condition in  $S_1$ . And we need to prove the following to show that  $S_1$  is interference free:

$$\{P_{10} \wedge Q_0\} S_1 \{Q_0\}$$
 (4)

$$\{P_{10} \land P_{00}\} S_1 \{P_{00}\}\$$
 (5)

$$\{P_{10} \wedge P_{01}\} S_1 \{P_{01}\}\$$
 (6)

We are going to use the following identities:

$$\begin{aligned} Q_0 \wedge Q_1 &= (x = A \vee y = B) \wedge done_0 = 1 \wedge done_1 = 1 \\ P_{00} \wedge Q_1 &= (x = A \vee y = B) \wedge done_0 = 0 \wedge done_1 = 1 \\ P_{10} \wedge Q_0 &= (x = A \vee y = B) \wedge done_0 = 1 \wedge done_1 = 0 \\ P_{00} \wedge P_{10} &= X = A \wedge Y = B \wedge done_0 = 0 \wedge done_1 = 0 \\ P_{00} \wedge P_{11} &= X = A \wedge y = B \wedge done_0 = 0 \wedge done_1 = 0 \\ P_{10} \wedge P_{01} &= x = A \wedge Y = B \wedge done_0 = 0 \wedge done_1 = 0 \end{aligned}$$

 $\bullet$  For (1), we have:

$$\{(x = A \lor y = B) \land done_0 = 0 \land done_1 = 1\}$$

$$x := X; (Y, done_0) := (1, 1)$$

$$\{done_1 = 1 \land (done_0 = 0 \to y = B) \land (done_0 = 1 \to (x = A \lor y = B))\}$$

We see that  $done_0 = 1$  and y = B after the execution and obviously  $x = A \lor y = B$ .

 $\bullet$  For (2), we have

$$\{X = A \land Y = B \land done_0 = 0 \land done_1 = 0\}$$

$$x := X; (Y, done_0) := (1, 1)$$

$$\{done_1 = 0 \land (done_0 = 0 \to Y = B) \land (done_0 = 1 \to (x = A \lor y = B))\}$$

Using the assignment axiom ( $\{X = A\} x := X \{x = A\}$  if we omit the auxiliary variables for clarity sake), we get that x = A holds after the execution. Also  $done_0 = 1$ , and obviously  $x = A \lor y = B$ .

 $\bullet$  For (3), we have

$$\{X = A \land y = B \land done_0 = 0 \land done_1 = 0\}$$

$$x := X; (Y, done_0) := (1, 1)$$

$$\{done_1 = 0 \land (done_0 = 0 \to y = B) \land (done_0 = 1 \to (x = A \lor y = B))\}$$

Exactly as (2).  $done_0 = 1$  after the execution, x = A holds and obviously  $x = A \lor y = B$ .

The idea behind (4), (5) and (6) is symmetrical to (1), (2) and (3), so the proof is skipped.

Now we can show the inference tree for the program in two parts. First of all, we have:

$$\frac{\{P_{00}\}S_{00}\{P_{01}\}\}\{P_{01}\}S_{01}\{Q_{0}\}\}}{\{P_{00}\}S_{0}\{Q_{0}\}} \frac{\{P_{10}\}S_{10}\{P_{11}\}\}\{P_{11}\}S_{11}\{Q_{1}\}\}}{\{P_{10}\}S_{1}\{Q_{1}\}}$$

$$\frac{\{P_{00}\}S_{0}\{Q_{0}\}\}}{\{P_{00}\wedge P_{10}\}S_{0}||S_{1}\{Q_{0}\wedge Q_{1}\}}$$
(7)

# gic axioms of assignment. Second line is rule of composi-

First line contains Hoare logic axioms of assignment. Second line is rule of composition. Third line is Owicki-Gries rule for interference free statements. We will use the intermediate result of (7) in the next part:

$$\frac{\{\ P_{00} \wedge P_{10}\ \}\ done_0 = 0; done_1 = 0\ \{\ P_{00} \wedge P_{10}\ \}\ \ \ \ (7)}{\{\ P_{00} \wedge P_{10}\ \}\ done_0 = 0; done_1 = 0; (S_0||S_1)\ \{\ Q_0 \wedge Q_1\ \}}$$

$$\{\ X = A \wedge Y = B\ \}\ x := X; Y := 1||y := Y; X := x\ \{\ x = A \vee y = B\ \}$$

Second line is rule of composition. Third line is auxiliary variable rule that gets rid of  $done_0$  and  $done_1$  and the result is the wanted specification.
